                    Definitions of Managed Objects
                        for Frame Relay Service

Status of this Memo

   This document specifies an Internet standards track protocol for the
   Internet community, and requests discussion and suggestions for
   improvements. Please refer to the current edition of the "Internet
   Official Protocol Standards" (STD 1) for the standardization state
   and status of this protocol. Distribution of this memo is unlimited.

Abstract

   This memo defines an extension to the Management Information Base
   (MIB) for use with network management protocols in Transmission
   Control Protocol/Internet Protocol-based (TCP/IP) internets. In
   particular, it defines objects for managing the frame relay service.

   This document obsoletes RFC 1604.

Table of Contents

1. The SNMP Management Framework

    The SNMP Management Framework presently consists of five major
    components:

    o   An overall architecture, described in RFC 2571 [1].

    o   Mechanisms for describing and naming objects and events for the
        purpose of management. The first version of this Structure of
        Management Information (SMI) is called SMIv1 and described in STD
        16, RFC 1155 [2], STD 16, RFC 1212 [3] and RFC 1215 [4]. The
        second version, called SMIv2, is described in STD 58, RFC 2578
        [5], STD 58, RFC 2579 [6] and STD 58, RFC 2580 [7].

    o   Message protocols for transferring management information. The
        first version of the SNMP message protocol is called SNMPv1 and
        described in STD 15, RFC 1157 [8]. A second version of the SNMP
        message protocol, which is not an Internet standards track
        protocol, is called SNMPv2c and described in RFC 1901 [9] and RFC
        1906 [10]. The third version of the message protocol is called
        SNMPv3 and described in RFC 1906 [10], RFC 2572 [11] and RFC 2574
        [12].

    o   Protocol operations for accessing management information. The
        first set of protocol operations and associated PDU formats is
        described in STD 15, RFC 1157 [8]. A second set of protocol
        operations and associated PDU formats is described in RFC 1905
        [13].

    o   A set of fundamental applications described in RFC 2573 [14] and
        the view-based access control mechanism described in RFC 2575
        [15].

A more detailed introduction to the current SNMP Management Framework
can be found in RFC 2570 [16].

Managed objects are accessed via a virtual information store, termed
the Management Information Base or MIB. Objects in the MIB are
defined using the mechanisms defined in the SMI.

This memo specifies a MIB module that is compliant to the SMIv2. A
MIB conforming to the SMIv1 can be produced through the appropriate
translations. The resulting translated MIB must be semantically
equivalent, except where objects or events are omitted because no
translation is possible (use of Counter64). Some machine readable
information in SMIv2 will be converted into textual descriptions in
SMIv1 during the translation process. However, this loss of machine
readable information is not considered to change the semantics of the
MIB.

2. Overview

These objects are used to manage a frame relay Service. At present,
this applies to the following value of the ifType variable in the
IF-MIB [26]:

        frameRelayService (44)

This section provides an overview and background of how to use this
MIB and other potential MIBs to manage a frame relay service.

2.1. Scope of MIB

The Frame Relay Service MIB supports Customer Network Management
(CNM) of a frame relay network service. Through the use of this and
other related MIBs, a frame relay service customer's NMS can monitor
the customer's UNI/NNI logical ports and PVCs. It provides customers
with access to configuration data, performance monitoring
information, and fault detection for the delivered frame relay
service. As an option, an SNMP agent supporting the Frame Relay
Service MIB may allow customer-initiated PVC management operations
such as creation, deletion, modification, activation, and
deactivation of individual PVCs. However, internal aspects of the
network (e.g., switching elements, line cards, and network routing
tables) are beyond the scope of this MIB.

The Frame Relay Service MIB models all interfaces and PVCs delivered
by a frame relay service within a single virtual SNMP system for the
purpose of comprehensively representing the customer's frame relay
service. The customer's interfaces and PVCs may physically exist on
one or more devices within the network topology. An SNMP agent

providing support for the Frame Relay Service MIB as well as other
appropriate MIBs to model a single virtual frame relay network
service is referred to as a Frame Relay Service (FRS) agent.
Internal communication mechanisms between the FRS agent and
individual devices within the frame relay network delivering the
service are implementation specific and beyond the scope of this MIB.

The customer's NMS will typically access the SNMP agent implementing
the Frame Relay Service MIB over a frame relay permanent virtual
connection (PVC). SNMP access over a frame relay PVC is achieved
through the use of SNMP over UDP over IP encapsulated in Frame Relay
according to STD 55, RFC2427 and ITU X.36 Annex D [23]. Alternate
access mechanisms and SNMP agent implementations are possible.

This MIB will NOT be implemented on user equipment (e.g., DTE). Such
devices are managed using the Frame Relay DTE MIB (RFC2115[18]).
However, concentrators may use the Frame Relay Service MIB instead of
the Frame Relay DTE MIB.

This MIB does not define managed objects for the physical layer.
Existing physical layer MIBs (e.g., DS1 MIB) and Interface MIB will
be used as needed in FRS Agent implementations.

This MIB supports frame relay PVCs. This MIB may be extended at a
later time to handle frame relay SVCs.

A switch implementation may support this MIB for the purpose of
configuration and control of the frame relay service beyond the scope
of traditional customer network management applications. A number of
objects (e.g. frLportTypeAdmin) support administrative actions that
impact the operation of frame relay switch equipment in the network.
This is reflected in the differences between the two MIB compliance
modules:

    o the frame relay service compliance module
       (frnetservCompliance), and

    o the frame relay switch compliance module
       (frnetSwitchCompliance).

The frame relay service compliance module does not support the
administrative control objects used for switch management.

2.2. Transiting Multiple Frame Relay Networks

   This MIB is only used to manage a single frame relay service offering
   from one network service provider. Therefore, if a customer PVC
   traverses multiple networks, then the customer must poll a different
   FRS agent within each frame relay network to retrieve the end-to-end
   view of service.

   Figure 1 illustrates a customer ("User B") NMS accessing FRS agents
   in three different frame relay networks (I, J, and K).

```
                    +----------------------------------+
                    | Customer Network Management Station |
                    |            (SNMP based)          |
                    +----------------------------------+
                        ^           ^           ^
                        |           |           |
                        |           |           |
             UNI        |   NNI     |   NNI     |     UNI
              |         ^    |      ^    |      ^       |
              |  +----------+ | +----------+ | +----------+ |
              |  |          | | |          | | |          | |
   Originating |  |    FR    | | |    FR    | | |    FR    | |Terminating
   +--------+ |  | Network I | | | Network J | | | Network K | | +--------+
   |        | |  |          | | |          | | |          | | |        |
   |        | |---|          | |---|          | |---|          |---| User B |
   |        | |  |          | | |          | | |          | | |        |
   |     ////////////////////////////////////////////////////////////////// |
   |        | |  |          | | |          | | |          | | |        |
   +--------+ |  +----------+ | +----------+ | +----------+ | +--------+
              |              |              |              |
              |              |              |              |
              | PVC Segment 1 | PVC Segment 2 | PVC Segment 3 |
              |<------------->|<------------->|<------------->|
              |                                              |
              |          Multi-network PVC                   |
              |<-------------------------------------------->|
              |    NNI = Network-to Network Interface        |
                   UNI = User-to-Network Interface
```
                     Figure 1, Multi-network PVC

2.3. Access Control

   A frame relay network is shared amongst many frame relay subscribers.
   Each subscriber will only have access to their information (e.g.,
   information with respect to their interfaces and PVCs). The FRS agent
   should provide instance level granularity for MIB views.

2.4. Frame Relay Service MIB Terminology

   Access Channel - An access channel generically refers to the DS1/E1
   or DS3/E3-based UNI access channel or NNI access channel across which
   frame relay data transits. An access channel is the access pathway
   for a single stream of user data.

   Within a given DS1 line, an access channel can denote any one of the
   following:

   o Unchannelized DS1 - the entire DS1 line is considered an access
      channel. Each access channel is comprised of 24 DS0 time slots.

   o Channelized DS1 - an access channel is any one of 24 channels.
      Each access channel is comprised of a single DS0 time slot.

   o Fractional DS1 - an access channel is a grouping of NxDS0 time
      slots (NX56/64 Kbps, where N = 1-23 DS0 Time slots per Fractional
      DS1 Access Channel) that may be assigned in consecutive or
      non-consecutive order.

   Within a given E1 line, a channel can denote any one of the following:

   o Unchannelized E1 - the entire E1 line is considered a single
      access channel. Each access channel is comprised of 31 E1 time
      slots.

   o Channelized E1 - an access channel is any one of 31 channels.
      Each access channel is comprised of a single E1 time slot.

   o Fractional E1 - an access channel is a grouping of N E1 time
      slots (NX64 Kbps, where N = 1-30 E1 time slots per FE1 access
      channel) that may be assigned in consecutive or non-consecutive
      order.

   Within a given unformatted line, the entire unformatted line is
   considered an access channel. Examples include RS-232, V.35, V.36 and
   X.21 (non-switched), and unframed E1 (G.703 without G.704).

   Access Rate - The data rate of the access channel, expressed in
   bits/second. The speed of the user access channel determines how
   rapidly the end user can inject data into the network.

   Bc - The Committed Burst Size (Bc) is the maximum amount of
   subscriber data (expressed in bits) that the network agrees to
   transfer, under normal conditions, during a time interval Tc.

Be - The Excess Burst Size (Be) is the maximum amount of subscriber
data (expressed in bits) in excess of Bc that the network will
attempt to deliver during the time interval Tc. This data (Be) is
delivered in general with a lower probability than Bc.

CIR - The Committed Information Rate (CIR) is the subscriber data
rate (expressed in bits/second) that the network commits to deliver
under normal network conditions. CIR is averaged over the time
interval Tc (CIR = Bc/Tc).

DLCI - Data Link Connection Identifier

Logical Port - This term is used to model the frame relay "interface"
on a device.

NNI - Network to Network Interface

Permanent Virtual Connection (PVC) - A virtual connection that has
its end-points and bearer capabilities defined at subscription time.

Time slot (E1) - An octet within the 256-bit information field in
each E1 frame is defined as a time slot. Time slots are position
sensitive within the 256-bit information field. Fractional E1 service
is provided in contiguous or non-contiguous time slot increments.

Time slot (DS0) - An octet within the 192-bit information field in
each DS1 frame is defined as a time slot. Time slots are position
sensitive within the 192-bit information field. Fractional DS1
service is provided in contiguous or non-contiguous time slot
increments.

UNI - User to Network Interface

N391 - Full status (status of all PVCs) polling counter

N392 - Error threshold

N393 - Monitored events count

T391 - Link integrity verification polling timer

T392 - Polling verification timer

nT3 - Status enquiry timer

nN3 - Maximum status enquiry counter

2.5. Relation to Other MIBs

2.5.1. System Group

   Use the System Group of the SNMPv2-MIB [27] to describe the Frame
   Relay Service (FRS) agent. The FRS agent may be monitoring many
   frame relay devices in one network. The System Group does not
   describe frame relay devices monitored by the FRS agent.

   sysDescr: ASCII string describing the FRS agent.
              Can be up to 255 characters long. This field is
              generally used to indicate the network providers
              identification and type of service offered.

   sysObjectID: Unique OBJECT IDENTIFIER (OID) for the
                 FRS agent.

   sysUpTime: Clock in the FRS agent; TimeTicks
               in 1/100s of a second. Elapsed type since
               the FRS agent came on line.

   sysContact: Contact for the FRS agent.
                ASCII string of up to 255 characters.

   sysName: Domain name of the FRS agent, for example,
             acme.com

   sysLocation: Location of the FRS agent.
                 ASCII string of up to 255 characters.

   sysServices: Services of the managed device. The value "2",
                 which implies that
                 the frame relay network is providing
                 a subnetwork level service, is recommended.

2.5.2. Interfaces Table (ifTable, ifXtable)

   This specifies how the Interfaces Group defined in the IF MIB [26]
   shall be used for the management of frame relay based interfaces, and
   in conjunction with the Frame Relay Service MIB module. This memo
   assumes the interpretation of the evolution of the Interfaces group
   to be in accordance with: "The interfaces table (ifTable) contains
   information on the managed resource's interfaces. Each sub-layer
   below the internetwork layer of a network interface is considered an
   interface." Thus, the ifTable allows the following frame relay-based
   interfaces to be represented as table entries:

    - Frame relay interfaces in equipment (e.g., switches, routers or
       networks) supporting frame relay. This level is concerned with
       generic frame counts and not with individual virtual connections.

    In accordance with the guidelines of ifTable, frame counts per
    virtual connection are not covered by ifTable, and are considered
    interface specific and covered in the Frame Relay Service MIB module.
    In order to interrelate the ifEntries properly, the Interfaces Stack
    Group shall be supported.

    Some specific interpretations of ifTable for frame relay follow.

    Object   Use for the generic Frame Relay layer
    ======   ===
    ifIndex   Each frame relay port is represented by an
                              ifEntry.

    ifDescr   Description of the frame relay interface.
                              ASCII string describing the UNI/NNI logical
                              port. Can be up to 255 characters long.

    ifType   The value allocated for Frame Relay Service
                              is equal to 44.

    ifMtu   Set to maximum frame size in octets for this
                              frame relay logical port.

    ifSpeed   Peak bandwidth in bits per second available
                              for use. This could be the speed of the
                              logical port and not the access rate. Actual
                              user information transfer rate (i.e., access
                              rate) of the UNI or NNI logical port in bits
                              per second (this is not the clocking speed).
                              For example, it is 1,536,000 bits per second
                              for a DS1-based UNI/NNI logical port and
                              1,984,000 bits per second for an E1-based
                              UNI/NNI logical port.

    ifPhysAddress   The primary address for this logical port
                              assigned by the frame relay interface
                              provider. An octet string of zero length if
                              no address is used for this logical port.

    ifAdminStatus   The desired administrative status of the
                              frame relay logical port.

    ifOperStatus   The current operational status of the Frame
                          Relay UNI or NNI logical port.

    ifLastChange   The value of sysUptime at the last
                          re-initialization of the logical port. The
                          value of sysUpTime at the time the logical
                          port entered its current operational state.
                          If the current state was entered prior to the
                          last re-initialization of the local network
                          management subsystem, then this object
                          contains a zero value.

    ifInOctets   The number of received octets. This counter
                          only counts octets from the beginning of the
                          frame relay header field to the end of user
                          data.

    ifInUcastPkts   The number of received unerrored, unicast
                          frames.

    ifInDiscards   The number of received frames discarded.
                          Specifically, frames discarded due to ingress
                          buffer congestion and traffic policing.

    ifInErrors   The number of received frames that are
                          discarded because of an error. Specifically,
                          frames that are too long or too short, frames
                          that are not a multiple of 8 bits in length,
                          frames with an invalid or unrecognized DLCI,
                          frames with an abort sequence, frames with
                          improper flag delimitation, and frame that
                          fail FCS.

    ifInUnknownProtos   The number of packets discarded because of an
                          unknown or unsupported protocol. For Frame
                          Relay Service interfaces, this counter will
                          always be zero.

    ifOutOctets   The number of transmitted octets. This
                          counter only counts octets from the beginning
                          of the frame relay header field to the end of
                          user data.

    ifOutUcastpkts   The number of unerrored, unicast frames sent.

    ifOutDiscards   The number of frames discarded in the egress
                          direction. Possible reasons are as follows:
                          policing, congestion.

   ifOutErrors   The number of frames discarded in the egress
                              direction because of an error. Specifically,
                              frames that are aborted due to a transmitter
                              underrun.

   ifName   This variable is not applicable for Frame
                              Relay Service interfaces, therefore, this
                              variable contains a zero-length string.

   ifInMulticastPkts   The number of received unerrored, multicast
                              frames.

   ifInBroadcastPkts   This variable is not applicable for Frame
                              Relay Service interfaces, therefore, this
                              counter is always zero.

   ifOutMulticastPkts   The number of sent unerrored, multicast
                              frames.

   ifOutBroadcastPkts   This variable is not applicable for Frame
                              Relay Service interfaces, therefore, this
                              counter is always zero.

   ifHCInOctets   Only used for DS3-based (and greater) Frame
                              Relay logical ports. The number of received
                              octets. This counter only counts octets
                              from the beginning of the frame relay header
                              field to the end of user data.

   ifHCOutOctets   Only used for DS3-based (and greater) Frame
                              Relay logical ports. The number of
                              transmitted octets. This counter only counts
                              octets from the beginning of the frame relay
                              header field to the end of user data.

   ifLinkUpDownTrapEnable Set to true(1). It is recommended that the
                              underlying physical layer notifications be
                              disabled since both are not required.
                              Notifications are enabled at the frame relay
                              service layer specifically because PVC
                              notifications are not to be sent if the frame
                              relay interface fails. Without a
                              linkUp/linkDown notification, the management
                              station would receive no notification of the
                              failure.

        ifHighSpeed   Set to the user data rate of the frame relay
                                  logical port in millions of bits per second.
                                  If the user data rate is less than 1 Mbps,
                                  then this value is zero.

        ifPromiscuousMode   Set to false(2).

        ifConnectorPresent   Set to false(2).

   Frame relay network service interfaces support the Interface Stack
   Group. Frame relay network service interfaces do not support any
   other groups or objects in the Interfaces group of the IF MIB.

2.5.3. Stack Table for DS1/E1 Environment

   This section describes by example how to use ifStackTable to
   represent the relationship of frame relay service to ds0 and
   ds0Bundles with ds1 interfaces [20].

   Example: A frame relay service is being carried on 4 ds0s of a ds1.

```
      +--------------------+
      | Frame Relay Service |
      +--------------------+
               |
      +--------------------+
      | ds0Bundle          |
      +--------------------+
        |     |    |     |
      +---+ +---+ +---+ +---+
      |ds0| |ds0| |ds0| |ds0|
      +---+ +---+ +---+ +---+
        |     |    |     |
      +--------------------+
      | ds1                |
      +--------------------+
```

   The assignment of the index values could for example be:

```
        ifIndex   Description
        1         FrameRelayService (type 44)
        2         ds0Bundle         (type 82)
        3         ds0 #1            (type 81)
        4         ds0 #2            (type 81)
        5         ds0 #3            (type 81)
        6         ds0 #4            (type 81)
        7         ds1               (type 18)
```

The ifStackTable is then used to show the relationships between the
various interfaces.

```
        ifStackTable Entries

        HigherLayer    LowerLayer
        0              1
        1              2
        2              3
        2              4
        2              5
        2              6
        3              7
        4              7
        5              7
        6              7
        7              0
```

In the case where the frame relay service is using a single ds0, then
the ds0Bundle is not required.
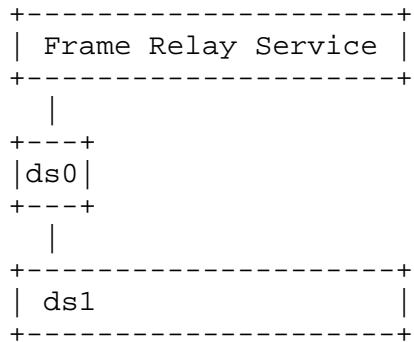

```
    +---------------------+
    | Frame Relay Service |
    +---------------------+
       |
    +---+
    |ds0|
    +---+
       |
    +---------------------+
    | ds1                 |
    +---------------------+
```

The assignment of the index values could for example be:

```
        ifIndex   Description
        1         FrameRelayService (type 44)
        2         ds0               (type 81)
        3         ds1               (type 18)
```

The ifStackTable is then used to show the relationships between the
various interfaces.

        ifStackTable Entries

        HigherLayer   LowerLayer
        0   1
        1   2
        2   3
        3   0

2.5.4.   Stack Table for V.35 Environments

   This section describes by example how to use ifStackTable to
   represent the relationship of frame relay service with V.35
   interfaces.

        +--------------------+
        | Frame Relay Service |
        +--------------------+
                  |
        +--------------------+
        | v35 |
        +--------------------+
   An example of index values in this case could be:

           ifIndex   Description
           1   FrameRelayService (type 44)
           2   v35   (type 33)

   Note type 33 (RS232-like MIB) is used instead of type 45 (V.35). V35
   does not pertain to this environment.

   The ifStackTable is then used to show the relationships between the
   various interfaces.

           ifStackTable Entries

        HigherLayer   LowerLayer
        0   1
        1   2
        2   0

2.5.5.   The Frame Relay/ATM PVC Service Interworking MIB

   Connections between two frame relay endpoints are represented with an
   entry in the frPVCConnectTable of this MIB. Both endpoints are
   represented with rows in the frPVCEndptTable. The
   frPVCEndptConnectIdentifier object of each endpoint points to the
   frPVCConnectTable cross-connect table row for the connection.

   In contrast, a connection that spans frame relay and ATM endpoints is
   represented with an entry in the frAtmIwfConnectionTable of the
   FR/ATM PVC Service Interworking MIB defined in [28].

   In the case of an inter-worked connection, the
   frPVCEndptConnectIdentifier object is set to zero. Instead, the
   frPVCEndptAtmIwfConnIndex object is set to the index of the FR/ATM
   IWF cross-connect table row.

   The frame relay PVC cross-connect table (frPVCConnectTable) does not
   contain an entry for the FR/ATM inter-worked connection.

2.6. Textual Convention Change

   Version 1 of the Frame Relay Service MIB contains MIB objects defined
   with the DisplayString textual convention. In version 2 of this MIB,
   the syntax for these objects has been updated to use the (now
   preferred) SnmpAdminString textual convention. The new TC provides
   support for a greater variety of international character sets.

   The working group realizes that this change is not strictly supported
   by SMIv2. In our judgment, the alternative of deprecating the old
   objects and defining new objects would have a more adverse impact on
   backward compatibility and interoperability, given the particular
   semantics of these objects.

3. Object Definitions

        REVISION "200009280000Z"
        DESCRIPTION
            "Published as RFC 2954.

            The major new features of this revision include:

                o  Support for read-write capability to
                   provision switch components providing service,

                o  Support for cross-connection via a frame relay
                   to ATM service interworking function,

                o  Support for frame relay fragmentation,

                o  Additional frame counters to track frame
                   loss.

            Refer to Appendix A for a comprehensive list of
            changes since RFC 1604."

            SYNTAX   OBJECT IDENTIFIER
            MAX-ACCESS   read-only
            STATUS   deprecated
            DESCRIPTION
                    "The value of this object is used as a pointer to
                    the table that contains the Local In-Channel
                    Signaling Protocol parameters and errors for this
                    UNI/NNI logical port.

                    This object has been deprecated to reflect the
                    fact that the local in-channel signaling
                    parameters are accessed from a single table
                    (frMgtVCSigTable) that includes parameters for all
                    possible signaling protocols. Early design
                    anticipated multiple tables, one for each
                    signaling protocol."
            ::= { frLportEntry 7 }

        frLportDLCIIndexValue OBJECT-TYPE
            SYNTAX   Integer32 (16..4194303)
            MAX-ACCESS   read-only
            STATUS   current
            DESCRIPTION
                    "This object contains a hint to be used for
                    frPVCEndptDLCIIndex when creating entries in the
                    frPVCEndptTable. The SYNTAX of this object
                    matches the SYNTAX of the frPVCEndptDLCIIndex - an
                    object that is restricted to legal Q.922 DLCI
                    values for the size of the address field.

                    The value 0 indicates that no unassigned entries
                    are available.

                    To obtain the frPVCEndptDLCIIndex value for a new
                    entry, the manager issues a management protocol
                    retrieval operation to obtain the current value of

                    this object. After each retrieval, the agent must
                    modify the value to the next unassigned index to
                    prevent assignment of the same value to multiple
                    management systems.

                    A management system should repeat the read to
                    obtain a new value should an attempt to create the
                    new row using the previously returned hint fail."

        --
        -- Frame Relay PVC End-points
        --

        frPVCEndptTable OBJECT-TYPE
            SYNTAX   SEQUENCE OF FrPVCEndptEntry
            MAX-ACCESS   not-accessible
            STATUS   current
            DESCRIPTION
                    "The Frame Relay PVC End-Point table. This table
                    is used to model a PVC end-point. This table
                    contains the traffic parameters and statistics for
                    a PVC end-point.

                    This table is used to identify the traffic
                    parameters for a bi-directional PVC segment end-

point, and it also provides statistics for a PVC
segment end-point.

A PVC segment end-point is identified by a UNI/NNI
logical port index value and DLCI index value.

If the frame relay service provider allows the
frame relay CNM subscriber to create, modify or
delete PVCs using SNMP, then this table is used to
identify and reserve the requested traffic
parameters of each PVC segment end-point. The
Connection table is used to 'connect' the end-
points together. Not all implementations will
support the capability of
creating/modifying/deleting PVCs using SNMP as a
feature of frame relay CNM service.

Uni-directional PVCs are modeled with zero valued
traffic parameters in one of the directions (In or
 Out direction) in this table.

To create a PVC, the following procedures shall be
followed:

1) Create the entries for the PVC segment
    endpoints in the frPVCEndptTable by specifying
    the traffic parameters for the bi-directional
    PVC segment endpoints. As shown in figure 2, a
    point-to-point PVC has two endpoints, thus two
    entries in this table. Uni-directional PVCs
    are modeled with zero valued traffic
    parameters in one direction; all the 'In'
    direction parameters for one frame relay PVC
    End-point or all the 'Out' direction
    parameters for the other frame relay PVC
    Endpoint.

       frPVCEndptRowStatus OBJECT-TYPE
           SYNTAX   RowStatus
           MAX-ACCESS read-create
           STATUS   current
           DESCRIPTION
                    "This object is used to create new rows in this
                    table, modify existing rows, and to delete
                    existing rows. To create a new PVC, the entries
                    for the PVC segment end-points in the
                    frPVCEndptTable must first be created. Next, the
                    frPVCConnectTable is used to associate the frame
                    relay PVC segment end-points. In order for the
                    manager to have the necessary error diagnostics,
                    the frPVCEndptRowStatus object must initially be
                    set to 'createAndWait(5)'. While the
                    frPVCEndptRowStatus object is in the
                    'createAndWait(5)' state, the manager can set each
                    columnar object and get the necessary error
                    diagnostics. The frPVCEndptRowStatus object may
                    not be set to 'active(1)' unless the following
                    columnar objects exist in this row:
                    frPVCEndptInMaxFrameSize, frPVCEndptInBc,
                    frPVCEndptInBe, frPVCEndptInCIR,
                    frPVCEndptOutMaxFrameSize, frPVCEndptOutBc,
                    frPVCEndptOutBe, and frPVCEndptOutCIR."
              ::= { frPVCEndptEntry 11 }

           MAX-ACCESS read-only
           STATUS   current
           DESCRIPTION
                    "The value of this object identifies the PVC
                    status received via the local in-channel signaling

                    procedures for this PVC end-point. This object is
                    only pertinent for interfaces that perform the
                    bidirectional procedures.

                    Each value has the following meaning:
                      deleted(1): This PVC is not listed in the full
                                   status reports received from the
                                   user device. The object retains
                                   this value for as long as the PVC
                                   is not listed in the full status
                                   reports

                      active(2):   This PVC is reported as active, or
                                   operational, by the user device.

                        inactive(3): This PVC is reported as inactive,
                                     or non-operational, by the user
                                     device.

                        none(4):   This interface is only using the
                                     network-side in-channel signaling
                                     procedures, so this object does
                                     not apply."

      frPVCEndptAtmIwfConnIndex OBJECT-TYPE
          SYNTAX      Integer32  (0..2147483647)
          MAX-ACCESS  read-only
          STATUS      current
          DESCRIPTION
                  "This object contains the index value of the
                  FR/ATM cross-connect table entry used to link the
                  frame relay PVC with an ATM PVC.

                  Each row of the frPVCEndptTable that is not
                  cross-connected with an ATM PVC must return the
                  value zero when this object is read.

                  The value of this object is initialized by the
                  agent after the associated entries in the
                  frAtmIwfConnectionTable have been created.

                  The value of this object is reset to zero
                  following destruction of the associated entry in
                  the frAtmIwfConnectionTable"
          ::= { frPVCEndptEntry 31 }

      --
      -- Frame Relay PVC Connections
      --

      frPVCConnectIndexValue OBJECT-TYPE
          SYNTAX      INTEGER (0..2147483647)
          MAX-ACCESS  read-only
          STATUS      current
          DESCRIPTION
                  "This object returns a hint to be used for
                  frPVCConnectIndex when creating entries in the
                  frPVCConnectTable.

                  The value 0 indicates that no unassigned entries
                  are available.

                  To obtain the frPVCConnectIndex value for a new
                  entry, the manager issues a management protocol
                  retrieval operation to obtain the current value of
                  this object.  After each retrieval, the agent must
```

                    modify the value to the next unassigned index to
                    prevent assignment of the same value to multiple
                    management systems.

                    A management system should repeat the read to
                    obtain a new value should an attempt to create the
                    new row using the previously returned hint fail."
          ::= { frnetservObjects 4 }

      frPVCConnectTable OBJECT-TYPE
          SYNTAX   SEQUENCE OF FrPVCConnectEntry
          MAX-ACCESS   not-accessible
          STATUS   current
          DESCRIPTION
                    "The Frame Relay PVC Connect Table is used to
                    model the bi-directional PVC segment flows
                    including: point-to-point PVCs, point-to-
                    multipoint PVCs, and multipoint-to-multipoint
                    PVCs.

                    This table has read-create access and is used to
                    associate PVC end-points together as belonging to
                    one connection. The frPVCConnectIndex is used to
                    associate all the bi-directional flows. Not all
                    implementations will support the capability of
                    creating/modifying/deleting PVCs using SNMP as a
                    feature of frame relay CNM service.

                    Once the entries in the frPVCEndptTable are
                    created, the following step are used to associate
                    the PVC end-points as belonging to one PVC
                    connection:

                    1) Obtain a unique frPVCConnectIndex
                        using the frPVCConnectIndexValue object.

                    2) Connect the PVC segment endpoints together
                        with the applicable frPVCConnectIndex value
                        obtained via frPVCConnectIndexValue. The
                        entries in this table are created by using
                        the frPVCConnectRowStatus object.

                    3) The agent will provide the value of the
                        corresponding instances of
                        frPVCEndptConnectIdentifier with the
                        frPVCConnectIndex value.

                    4) Set frPVCConnectAdminStatus to 'active(1)' in

all rows for this PVC segment to turn the
PVC on.

For example, the Frame Relay PVC Connection Group
models a bi-directional, point-to-point PVC
segment as one entry in this table.

```
Frame Relay                                    Frame Relay
 Network                                         Network
 Low Port                                       High Port

                 _____
                |                                   |
       _____|  >> from low to high PVC flow  >> |_____
                |  << from high to low PVC flow  <<  |
                |_____|
```

The terms low and high are chosen to represent
numerical ordering of a PVC segment's endpoints
for representation in this table. That is, the
endpoint with the lower value of ifIndex is termed
'low', while the opposite endpoint of the segment
is termed 'high'. This terminology is to provide
directional information; for example the
frPVCConnectL2hOperStatus and
frPVCConnectH2lOperStatus as illustrated above.

If the Frame Relay Connection table is used to
model a unidirectional PVC, then one direction
(either from low to high or from high to low) has
 its Operational Status equal to down.

 A PVC segment is a portion of a PVC that traverses
one Frame Relay Network, and a PVC segment is
identified by its two end-points (UNI/NNI logical
port index value and DLCI index value) through one
Frame Relay Network."

            MAX-ACCESS read-only
            STATUS   current
            DESCRIPTION
                    "The value of this object identifies the current
                    operational status of the PVC segment connection
                    in one direction; (i.e., in the low to high
                    direction). This value affects the PVC status
                    indicated across the ingress NNI/UNI (low side) of
                    the PVC segment.

                    The values mean:

                    active(1)   - PVC is currently operational

                    inactive(2) - PVC is currently not operational.
                                  This may be because of an underlying
                                  LMI or DS1 failure.

                    testing(3) - PVC is currently undergoing a test.
                                  This may be because of an underlying
                                  frLport or DS1 undergoing a test.

                      unknown(4) - the status of the PVC currently can
                                    not be determined."

         frnetservCompliance2 MODULE-COMPLIANCE
             STATUS       current
             DESCRIPTION
                     "The compliance statement for SNMP entities which
                     have Frame Relay Network Service Interfaces.

                     The distinction between 'service' and 'switch' is
                     that a 'switch' is configured via this MIB.
                     Hence, the various read/write objects have write
                     capability.  A 'service' represents a passive
                     monitor-only customer network management
                     interface.  The various read/write objects are
                     restricted to read-only capability."

6. Security Considerations

   There are a number of management objects defined in this MIB that
   have a MAX-ACCESS clause of read-write and/or read-create. Such
   objects may be considered sensitive or vulnerable in some network
   environments. The support for SET operations in a non-secure
   environment without proper protection can have a negative effect on
   network operations.

   No managed objects in this MIB contain sensitive information.

SNMPv1 by itself is not a secure environment. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB.

It is recommended that the implementers consider the security features as provided by the SNMPv3 framework. Specifically, the use of the User-based Security Model RFC 2574 [12] and the View-based Access Control Model RFC 2575 [15] is recommended.

It is then a customer/user responsibility to ensure that the SNMP entity giving access to an instance of this MIB, is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

APPENDIX A   Update Information

   The changes from RFC 1604 are the following:

   (1)   Added the object frLportDLCIIndexValue to automatically generate
          index values for new DLC rows.

   (2)   Add the following objects to support manager writing to objects:

          Logical Port Objects
              frLportTypeAdmin
              frLportVCSigProtocolAdmin

          VC Objects
              frMgtVCSigProcedAdmin
              frMgtVCSigUserN391Admin
              frMgtVCSigUserN392Admin
              frMgtVCSigUserN393Admin
              frMgtVCSigUserT391Admin
              frMgtVCSigNetN392Admin
              frMgtVCSigNetN393Admin
              frMgtVCSigNetT392Admin
              frMgtVCSigNetnT3Admin

   (3)   Add objects to control fragmentation:

          frLportFragControl frLportFragSize

   (4)   Added objects to track frames offered to network (in) and
          delivered (out) for increased visibility into policing-driven
          discards, congestion-driven discards, DE-bit setting, and
          congestion bit setting:

          frPVCEndptInDiscardsDESet
          frPVCEndptInFramesFECNSet
          frPVCEndptOutFramesFECNSet
          frPVCEndptInFramesBECNSet
          frPVCEndptOutFramesBECNSet
          frPVCEndptInCongDiscards
          frPVCEndptInDECongDiscards
          frPVCEndptOutCongDiscards
          frPVCEndptOutDECongDiscards
          frPVCEndptOutDEFrames

   (5)   Added the PVC object frPVCEndptAtmIwfConnIndex to identify the
          type of connection, frame relay or ATM IWF; and to identify the
          cross-connect row of the FR/ATM IWF MIB.

   (6) Added objects to provide printable names of the connection user
        and service provider:

        frPVCConnectUserName
        frPVCConnectProviderName

   (7) Added a new notification to correct flaws in the RFC1604 trap.
        The flaws include improper OID suffix (SMIv1 compatibility
        issue) and the inclusion of redundant index fields

   (8) Updated compliance modules and object groups to reflect the new
        objects and notification:

        frnetservCompliance2 -   New service-centric (read-only)
                                      compliance module

        frnetSwitchCompliance -   New switch-centric (read-write)
                                      compliance module

        frnetservCompliance -   Original RFC 1604 Module, now
                                      deprecated

        frnetservLportGroup -   Original RFC 1604 logical port
                                      group, now deprecated

        frnetservLportGroup2 -   Replacement logical port group

        frnetservPVCEndptGroup2 -   Extension objects with this
                                      revision of the MIB

        frnetservPVCConnectNamesGroup - New group w/ display names
                                      for connections

        frnetservLportAdminGroup - New group w/ read-write objects
                                      for the logical port

        frnetservMgtVCSigAdminGroup - New group w/ read-write objects
                                      for the signaling protocol

        frnetservPVCNotifGroup -   Group deprecated to eliminate
                                      obsolete frPVCConnectStatusChange
                                      notification

        frnetservPVCNotifGroup2 -   New group added with w/
                                      frPVCConnectStatusNotif

   (9) Added UNITS and REFERENCE clauses for objects that needed the
        clarification.

     (10) Changed references to "proxy-agent" to "FRS agent" to avoid
          confusion with other proxy-agent terminology.

     (11) Changed objects using the DisplayString TC to use the
          SnmpAdminString TC.

     (12) frMgtVCSigProced - Expanded to include the u2nuser(3)
          enumeration for the UNI protocol operation where the logical
          port operates in the user role.

     (13) DESCRIPTION text added to specify agent response when object is
          not instantiated for the following objects:

          frMgtVCSigUserN391
          frMgtVCSigUserN393
          frMgtVCSigUserT391
          frMgtVCSigUserN392
          frMgtVCSigNetN391
          frMgtVCSigNetN393
          frMgtVCSigNetT391
          frMgtVCSigNetN392
          frMgtVCSigNetnN4
          frMgtVCSigNetnT3
          frMgtVCSigUserLinkRelErrors
          frMgtVCSigUserProtErrors
          frMgtVCSigUserChanInactive

     (14) DESCRIPTION text addressing case of logical port not performing
          network-side procedures was removed from following objects:

          frMgtVCSigNetLinkRelErrors
          frMgtVCSigNetChanInactive
          frMgtVCSigNetProtErrors

     (15) frPVCEndptConnectIdentifier - Operation described for the case
          of FR/ATM IWF cross-connect operation.

     (16) frPVCEndptRcvdSigStatus - Added description of enumerated
          values.

     (17) frPVCEndptInDiscards - Clarified DESCRIPTION to state that
          congestion discards are not counted by object.

     (18) frPVCConnect{Low|High}IfIndex - Changed to use InterfaceIndex TC
          and changed reference to MIB-II to the new IF-MIB. Removed
          statement asserting that a zero value means the port is not a FR
          logical port.

(19) frPVCConnectIndex - Added a range to the SYNTAX clause

(20) frPVCConnect{L2h|H2l}OperStatus - Added DESCRIPTION text for
     each enumerated value.

(21) frAccountPVCDLCIIndex - Added a range to the SYNTAX clause

(22) frPVCOnnectStatusChange Notification - STATUS change to
     deprecated. Obsoleted to eliminate inappropriate inclusion of
     index objects

(23) frPVCConnectStatusNotif Notification - Replaces
     frPVCConnectStatusChange. In addition, the notification now
     requires 2 instances of the frPVCEndptRcvdSigStatus object, one
     for each endpoint of the connection.

(24) Guidance added to recommend ifLinkUpDownTrapEnable be set on.

(25) Behavior of the PVC status and endpoint signaling status is
     clarified for the case of underlying layer failure.

(26) Overview text re-written for clarity.

(27) Clarified role of system group.

(28) Established maximum frame size of 4096 and default value of
     1600.

(29) Clarified that DLC index range is restricted to valid range for
     the specific length of address field used on the logical port.

(30) Figure 1 and accompanying text was removed to eliminate a
     confusing "MIB stack" concept. See the section titled "Relation
     to Other MIBs" for replacement text.

Intellectual Property Rights

   The IETF takes no position regarding the validity or scope of any
   intellectual property or other rights that might be claimed to
   pertain to the implementation or use of the technology described in
   this document or the extent to which any license under such rights
   might or might not be available; neither does it represent that it
   has made any effort to identify any such rights. Information on the
   IETF's procedures with respect to rights in standards-track and
   standards-related documentation can be found in BCP-11. Copies of
   claims of rights made available for publication and any assurances of
   licenses to be made available, or the result of an attempt made to
   obtain a general license or permission for the use of such
   proprietary rights by implementers or users of this specification can
   be obtained from the IETF Secretariat.

   The IETF invites any interested party to bring to its attention any
   copyrights, patents or patent applications, or other proprietary
   rights which may cover technology that may be required to practice
   this standard. Please address the information to the IETF Executive
   Director.
